Acute Pain Management
Meeting the Challenges

U.S. Department of Veterans Affairs
Veterans Health Administration
PBM Academic Detailing Service
Meeting the Challenges of Acute Pain Management

Major changes have occurred in the treatment of pain with the focus now on a biopsychosocial model of pain care using multimodal treatments. A focused effort is needed to reduce harm to Veterans from unnecessary opioid prescribing and improve pain control in patients with acute pain conditions, including postoperative pain, by including non-pharmacological and non-opioid pain management approaches. With the right approach, we can reduce the number of Veterans who develop opioid use disorder and reduce overdose deaths.

What started the changes?¹,²

- Recognition of overdose deaths related to prescription opioids
- Increasing rates of opioid use disorder, heroin use, and other opioid related harms
- Lack of evidence that opioids work for long-term pain management

Despite knowledge of this, overdose deaths related to opioids continue to increase.

Figure 1. Overdose Deaths Involving Opioids 2000–2015¹

In 2015, overdoses involving opioids resulted in 33,091 deaths in the United States.¹
**Why is Treating Acute Pain with Opioids a Concern?**

We need to stop acute opioid use from turning into chronic use with possible worsening pain and functional ability, and the risk of progressing to opioid use disorder. To further address the opioid epidemic, we need to address how opioids are prescribed for acute pain.

**Figure 2.** For every 48 patients prescribed a new opioid in the emergency department 1 will become a long-term user

Retrospective analysis involving Medicare beneficiaries who had an index emergency department visit in the period from 2008 through 2011 and had not received prescriptions for opioids within 6 months before that visit. Sample consisted of 377,629 patients. Within individual hospitals, rates of opioid prescribing varied widely (7.3% vs. 24.1%). In addition, the providers who prescribed opioids the most had higher rates of patients continuing opioids long term compared to providers prescribing opioids at lower rates for acute pain.

The emergency department (ED) is a common place where opioid prescribing for acute pain occurs. In a review of ED prescribing in the Veterans Health Administration (VA) between 2009 and 2015, the overall VA ED opioid prescribing rate was 13.6%. The most common opioid prescribed was hydrocodone/acetaminophen, followed by tramadol and oxycodone/acetaminophen. The average quantity prescribed for these three opioids was 41 pills.

**Figure 3.** What Does this Mean for a Veteran who Presents to the ED

- At least 1 in 7 Veterans who are seen at a VA ED are given an opioid
- Risk of developing chronic use increases with every day of opioid prescribed
- Chronic use of opioids can lead to opioid use disorder in as many as 40% of users
Acute Pain

Clinical evidence supports the use of opioids for severe pain conditions involving surgery and significant trauma; however, the key is to use opioids only when necessary and for a limited duration to prevent chronic use.

This needs to be done in all settings where acute pain is treated.

- Dental clinics
- Surgery
- Primary care
- Inpatient settings and at discharge
- Emergency department

Acute pain in many cases may be successfully managed with non-pharmacological treatments and/or non-opioid medications.

Managing Acute Pain Safely and Effectively

To manage acute pain safely and effectively, first evaluate the severity of the pain based on the evaluation of the patient, diagnosis, and the patient’s feedback about the pain and impact of the pain on their functioning.

Figure 4. Step-wise Approach to Acute Pain Management

| Step 3 | Non-pharmacologic approaches +
|        | Non-opioid pharmacotherapy +/−
|        | Short term use (3–5 days) of short-acting opioids |
| Step 2 | Non-pharmacologic approaches +
|        | Non-opioid pharmacotherapy |
| Step 1 | Non-pharmacologic approaches |
Non-pharmacologic approaches should be considered first line for patients with acute pain. Since acute pain typically resolves over days to weeks, patients may only need these approaches for a short duration of time. Some treatments may be more appropriate immediately after an injury (e.g., ice, heat, stretching, and elevation), while others like physical therapy and exercise may be implemented once the patient is able to do more activities.

**Figure 5: Non-pharmacologic Treatments Options for Acute Pain**

**Step 1**

*Start with Non-pharmacologic Approaches*

- **Self Care**
  - Ice
  - Heat
  - Rest
  - Elevation of affected limb

- **Complementary and Integrative Therapies**
  - Acupuncture
  - Massage
  - Chiropractic therapy

- **Rehabilitation Therapies**
  - Physical therapy
  - Occupational therapy

- **Exercise**
  - Stretching
  - Swimming
  - Walking
  - Tai chi
  - Yoga
  - Chair exercises

---

2,10–15
Prospective randomized trial of acupuncture versus morphine to treat acute onset moderate to severe pain in emergency department patients. Each group consisted of 150 patients with pain for <72 hours, pain intensity of >40 (on visual analog scale (VAS) 0–100) with acute musculoskeletal pain with no evidence of fracture or dislocation, including ankle and knee sprains, shoulder and elbow tendonitis, upper and lower limb pain, low back pain without neurologic deficit, acute abdominal pain with no urgent surgical intervention and acute primary headache. Success rate and resolution time were both statistically significantly different and favored acupuncture.

Psychosocial factors can predict the progression of acute pain to chronic pain and disability.\textsuperscript{17,18} The three most common and influential factors include:

- **Catastrophizing**
  - Exaggerated and irrational thoughts about the pain the patient is experiencing
  - Viewing pain as a serious threat to the patient’s health and functioning

- **Fear avoidance**
  - Patient will avoid physical activity and movement due to fear that it will cause progression of the injury and/or increased pain

- **Depressed mood**
  - Associated with increased pain, lower pain tolerance, and reduction in quality of life

Patients experiencing these psychosocial factors may benefit from psychology-based treatments including:\textsuperscript{13–15,19–24}

- Cognitive behavioral therapy (CBT)
- Acceptance and commitment therapy (ACT)
- Mindfulness-based stress reduction (MBSR)
Consider Non-opioid Pharmacotherapy

Non-opioid pharmacotherapy should be considered for all types of acute pain where non-pharmacologic treatments are not effective or would not be considered effective as monotherapy.

Figure 7. Types of Non-opioid Pharmacotherapy

- **TOPICALS**: Consider for patients with localized or regional pain and intact skin.
- **ORAL THERAPY**: Consider for patients with systemic/widespread pain who cannot use or did not respond to topicals.

Figure 8. Topical Diclofenac Gel Provides Similar Reduction in Pain Compared to Oral Ibuprofen for Osteoarthritis of the Hand.²⁵

Double-blind randomized study of patients with activated osteoarthritis of the finger joints showed that diclofenac gel 10 cm ribbon applied 4 times a day was as effective as oral ibuprofen dosed at 400 mg three times daily. Secondary parameters of disease activity, pain at rest, pain on movement, morning stiffness, grip strength and quality of life all showed comparable improvements.
Products are listed based on evidenced based recommendations. Not all products listed may be available on VA National Formulary and could require non-formulary request or prior authorization request. To view VA National Formulary: [https://www.pbm.va.gov/PBM/NationalFormulary.asp](https://www.pbm.va.gov/PBM/NationalFormulary.asp).

NSAID

- Diclofenac formulations: gel, solution, or patch
- Used for localized/regional pain in a joint area like the knee, ankle, shoulder and wrist
  - Produces localized anti-inflammatory effects
  - Evidence does not support use for low back pain.
- Less systemic side effects compared to oral NSAIDs due to minimal systemic absorption
  - Safer to use in patients on oral anticoagulants

Lidocaine

- Lidocaine patch
- Used for peripheral neuropathic pain
- Blocks abnormal peripheral neuronal conduction
  - Provides local analgesia of painful skin where the medication is applied
- Systemic absorption is very low when applied to intact skin

Methyl Salicylate

- Methyl salicylate formulations: cream, ointment, or patch
  - Can be combined with menthol and/or camphor
- Used for local/regional effect for musculoskeletal pain
- Counterirritant causing mild inflammation which results in deeper pain relief
- Apply to intact skin

Capsaicin

- Capsaicin formulations: cream or ointment
- Used for peripheral neuropathic pain and musculoskeletal pain
- Depletes substance P with daily use leading to desensitization of sensory nerve fibers and resulting in less pain
- Must use multiple times a day every day to maintain effect
Oral Therapy

Selection of non-opioid medications should be made based on individual patient characteristics (e.g., type of pain, other medications, comorbidities).

Figure 10. Oral Therapy

**Acetaminophen**
- First line therapy for the treatment of osteoarthritis and musculoskeletal pain
- Not associated with GI ulcer; no significant platelet or anti-inflammatory effect at doses <2000 mg/day
- Maximum dosage 2000 mg daily in patients with liver disease and 4000 mg daily in patients without liver disease
  - Caution patients about acetaminophen in over-the-counter and combination products

**NSAIDs**
- First line agents for musculoskeletal pain and acute and chronic low back pain
  - May be more effective than acetaminophen, but are associated with more side effects (e.g., GI ulceration, CV effects including MI and stroke, and renal toxicity)
- Trial more than one NSAID, since there can be variability in patient response
- Black boxed warning to avoid perioperative use after CABG*
- Adding an NSAID to a pain regimen containing an opioid may have an opioid-sparing effect of approximately 20–35%

**Non-benzodiazepine Skeletal Muscle Relaxants (SMR)**
- Use for acute or exacerbation of chronic low back or neck pain with muscle spasms, for short term use only (<7 days)
- Drowsiness is common, avoid driving, operating heavy machinery, and alcohol
- Recommend against using carisoprodol due to potential for abuse and/or misuse
- Recommend against using benzodiazepines due to lack of benefit and higher risks

*Do not use perioperatively and avoid in the first 10–14 days after CABG surgery. CABG = coronary artery bypass graft; CV = cardiovascular; GI = gastrointestinal; MI = myocardial infarction; NSAID = nonsteroidal anti-inflammatory drug.
Concerns About Adverse Effects from NSAIDs

Gastrointestinal (GI) toxicity:

Figure 11. Gastrointestinal Toxicity—What are the Risks?\textsuperscript{38,40,41}

- Approximately 25% of chronic NSAID users will develop GI ulcer disease; 2 to 4% will bleed or perforate
- Consider COX-2 selective NSAIDs like meloxicam and etodolac which have lower GI risks than other NSAIDs
- Celecoxib (COX-2 inhibitor) has a lower risk of GI events compared to naproxen and ibuprofen but provides similar pain reduction

Table 1. Prevention of NSAID Induced GI and CV Toxicity\textsuperscript{38,39}

</tbody>
</table>

*High dose and long-term use (>1 year) of PPIs has been linked to side effects including: osteoporosis, Clostridium difficile associated diarrhea, pneumonia, and decreased absorption of magnesium and Vitamin B12. **Consider NSAID or COX-2 inhibitor that may have lower CV risks like naproxen, ibuprofen, or moderate dose celecoxib.

COX-2 inhibitor = cyclooxygenase 2 inhibitor; CV = cardiovascular; PPI = proton pump inhibitor.
Figure 12. Peptic Ulcer Bleeding Events Were Similar Between Users of Conventional NSAIDs Combined with PPIs Compared with Selective COX-2 Inhibitors Alone or Combined with PPIs

Case-control study from the Netherlands during the period of January 1998 to December 2012 in subjects who had ever used conventional NSAIDs and/or selective COX-2 inhibitors who were >18 years at first hospital admission with a primary discharge diagnosis of GI toxicity defined as peptic ulcer disease (PUD) in the GI tract. They identified 2,634 PUD cases and 5,074 age-matched controls that were current users of conventional NSAIDs or selective COX-2 inhibitors at the index date.

Cardiovascular Risks\textsuperscript{38,43,44}

- NSAIDs and COX-2 inhibitors can increase cardiovascular risk
  - Hypertension, stroke, myocardial infarction, and heart failure
  - Avoid use in patients with a history of heart failure or recent myocardial infarction
- Diclofenac and indomethacin appear to have higher risks
- Naproxen, ibuprofen, and moderate dose celecoxib (100 mg twice daily) may have a lower risk\textsuperscript{38}

Renal Risks\textsuperscript{45}

- Both COX-2 selective and nonselective NSAIDs are associated with renal side effects and may result in acute and chronic renal failure.
- Risk factors include:
  - Elderly
  - Dehydrated state
  - Other comorbidities like congestive heart failure, diabetes, and cirrhosis
Opioids have been shown to be effective for very short-term (3–5 days) treatment of severe acute pain (e.g., invasive surgery or significant trauma).\textsuperscript{3,46}

Consider opioids for patients with severe acute pain if:

1) The pain is not responding to non-pharmacologic or non-opioid treatments.

OR

2) The pain is not expected to respond to non-pharmacologic and/or non-opioid treatments alone.

</tbody>
</table>
Opioid prescribing by surgeons was evaluated at an institution for 5 common outpatient procedures where it was determined that opioids were overprescribed. Opioid prescribing guidelines were developed in an attempt to reduce the prescribing by 50% and also satisfy 80% of patients’ opioid requirements after surgery. Education was provided to surgeons and patients with recommendations to use a nonsteroidal anti-inflammatory drug and acetaminophen before using opioids. An analysis was done to reevaluate 246 patients undergoing the same surgical procedures showing a 53% reduction in total number of opioid pills prescribed by surgeons and only 1 patient (0.4%) required a refill of the opioid. An NSAID or acetaminophen was used by 85% of patients.

SLNB = sentinel lymph node biopsy.

Ibuprofen 400 mg was more effective in reducing pain than oxycodone 5 mg. No statistically significant difference in pain reduction between ibuprofen and ibuprofen + oxycodone.

Review of three randomized, double-blind clinical trials of single dose, oral ibuprofen plus oxycodone compared to placebo or the same dose of ibuprofen alone or oxycodone alone for acute postoperative pain from wisdom teeth removal or after abdominal or pelvic surgery.
It is important to weigh the risks vs benefits even when considering opioids for short-term use. Proceed with caution even if benefits of short-term use appear to outweigh risks.

**Factors that may increase the risk of acute opioid therapy extending to long-term opioid therapy:**

- Initiating long-acting opioids
- Initiating tramadol
  - >64% of patients started on tramadol for acute pain remained on tramadol after 1 year
  - ED visits associated with tramadol related adverse effects increased by 145% from 2005–2011
  - Adverse effects increase when tramadol is combined with benzodiazepines, opioid pain medications and/or alcohol
- Duration of opioid; risk increases every day an opioid is used
- Providing a second prescription or refill
- Prescribing a cumulative dose of 700 mg morphine equivalent or higher for the acute pain episode
  - Examples of prescriptions that exceed 700 mg morphine equivalent
    - Oxycodone 5 mg take 2 tablets every 4 hours (90 mg MEDD)
      - 720 mg morphine equivalent after 8 days at prescribed dose
    - Hydrocodone 10 mg/acetaminophen 325 mg 1 tablet every 4 hours (60 mg MEDD)
      - 720 mg morphine equivalent after 12 days at prescribed dose

**It only takes 3 days of opioid treatment to see an increase in the risk of acute therapy extending into long-term therapy.**

---

Educate patients on the effectiveness of NSAIDs and acetaminophen for post-surgical pain. If opioids are used, prescribe the smallest amount needed for the pain.
Figure 15: Any Use of Opioids for Acute Pain Increases the Probability of Chronic Opioid Use.  

![Graph showing the probability of continuing opioid use over time for different durations of opioid prescription.](image)

Records reviewed of patients > 18 years of age with at least one opioid prescription during June 1, 2006 – September 1, 2015 and >6 months of continuous enrollment without an opioid prescription before their first opioid prescription. A total of 1,294,247 patients met inclusion criteria, including 33,548 (2.6%) who continued opioid therapy for more than 1 year.

Figure 16. The Type of Opioid Prescribed for Acute Pain Can Increase the Probability of Developing Chronic Use.  

![Bar graph showing the probability of continued use for different types of opioids.](image)

Records reviewed of patients > 18 years of age who had at least one opioid prescription during June 1, 2006 – September 1, 2015 and >6 months of continuous enrollment without an opioid prescription before their first opioid prescription. A total of 1,294,247 patients met inclusion criteria, including 33,548 (2.6%) who continued opioid therapy for more than 1 year.
Not all patients with severe acute pain are good candidates for short-term opioid use.

**Contraindications to using opioids**

- True life-threatening allergy to opioids
- Actively prescribed and using benzodiazepine(s)
- Active substance use disorder (SUD)
- Elevated suicide risk

*Exception may be considered in patients with severe pain in an inpatient setting or controlled environment. Extra precautions will need to be taken to ensure patient safety.*

---

**Figure 17. Tips to Consider When Prescribing Opioid Therapy for Acute Pain**

- Check prescription drug monitoring program (PDMP) prior to prescribing opioids
- Prescribe no more than a 3–5 day supply; reassess Veteran for the need for continued opioids
- Extend to 7 days if pain condition will take longer to improve*
- Only use short acting, immediate release (IR) formulations**
- Encourage patients to safely dispose of any left over opioid medications using take-back events or mail-back packages
- Provide patient education about opioid risks and alternatives to opioid therapy should be offered

*If treatment is needed for longer than 5 days, evaluate the patient before prescribing another opioid prescription. **Risk of overdose is higher when using sustained release opioids in patients who are opioid naïve.*
Clinical Pearls for Managing Acute Low Back Pain

Low back pain is one of the most common reasons for people to see a provider with almost 25% of Americans reporting low back pain ≥1 day in the past 3 months.58

Patients are commonly prescribed an NSAID along with an opioid and/or a skeletal muscle relaxant, however there is very little evidence to support this type of combination therapy for acute low back pain.

Figure 18. No Statistically Significant Difference in Disability Score Improvement at One Week for the Treatment of Acute Low Back Pain59

Randomized double-blinded study in patients with acute, nontraumatic, nonradicular low back pain in the ED. Differences in RMDQ scores were not statistically significant. RMDQ = Roland-Morris Disability Questionaire. It is a 24-item questionnaire used to measure low back pain and related functional impairments. APAP = acetaminophen

Treatment of acute or subacute low back pain11

- First line: Non-pharmacologic treatment
- Second line: Nonsteroidal anti-inflammatory drugs (NSAIDs) or short-term course of non-benzodiazepine skeletal muscle relaxants
- Pain improves over time regardless of treatment provided
Managing Severe Acute Pain in Patients with Opioid Use Disorder (OUD)

Medication-assisted treatment (MAT) for OUD does not exclude a person from receiving treatment for acute pain, however it is still important to weigh the risks and benefits of pain management strategies.\textsuperscript{60–62}

Treatment of acute pain in patients with OUD on MAT should be done in coordination with a pain specialist and MAT prescriber.

Care coordination for perioperative pain management for patients on MAT is critical and should include at a minimum the MAT prescriber, anesthesiologist, and the surgeon.

Medication-assisted treatment (MAT) for patients with OUD

✓ 1st line: Buprenorphine/naloxone or Methadone
✓ 2nd line: Intramuscular Naltrexone

Relapse Prevention in Patients with OUD

Patients with OUD in remission are at very high risk for relapse when taking opioids for the treatment of pain.\textsuperscript{63–66}

- If relapse is identified, do not abruptly discontinue opioid treatment without providing addiction treatment
  - Abruptly discontinuing the opioid without addiction treatment in place sets the patient up for progression of an active disease
- Ensure Veteran has follow up with his/her provider who is monitoring the OUD therapy
- Provide overdose education and prescribe naloxone for patients to have at home
Opioid Overdose Education and Naloxone Distribution (OEND)\textsuperscript{67}

- Education and training for patients, family members, housemates and significant others on how to prevent, recognize, and respond to an opioid overdose
- Naloxone is available for outpatient dispensing

Figure 19. Basic Steps for Responding to an Opioid Overdose

1. Check for a response.
2. Give naloxone and call 911.
3. Ensure airway is open.
4. Consider naloxone again.\* 
5. Place in recovery position.

\*If the person does not start breathing in 2–3 minutes, give the second dose of naloxone; naloxone wears off quickly so a second dose may also be needed if the person stops breathing again.

Patients with OUD have a high risk of overdose when taking opioid medication for pain. Provide naloxone to all Veterans with OUD.
Summary

Opioids are no longer first line treatments for most types of acute pain.

Non-pharmacologic and non-opioid treatments should be used first line for most types of pain.

Reserve opioids for severe pain that is not expected to respond or has not responded to non-pharmacologic and non-opioid therapy.

When opioids are used, prescribe immediate release opioids for no more than 3 to 5 days. Reassess the patient before continuing opioids.

Treat acute pain in patients with opioid use disorder. If opioids need to be used, ensure follow-up to prevent relapses and provide naloxone.
