**Nivolumab (OPDIVO)**  
**National Drug Monograph**  
**March 2016**  
VA Pharmacy Benefits Management Services, Medical Advisory Panel, and VISN Pharmacist Executives

*The purpose of VA PBM Services drug monographs is to provide a focused drug review for making formulary decisions. Updates will be made when new clinical data warrant additional formulary discussion. Documents will be placed in the Archive section when the information is deemed to be no longer current.*

### FDA Approval Information

**Description/Mechanism of Action**  
Nivolumab is a monoclonal antibody that binds to the programmed-death 1 (PD-1) receptor on T-cells, blocking its interaction with its ligands PD-L1 and PD-L2 releasing PD-1 mediated pathway inhibition of the immune system resulting in anti-tumor responses. In combination with ipilimumab, another immune system checkpoint inhibitor, in melanoma results in greater T-cell function and better responses than either agent alone.

**Indication(s) Under Review in this document (may include off label)**  
- Unresectable or metastatic melanoma:  
  - As a single agent for BRAF V600 wild-type unresectable or metastatic melanoma.  
  - As a single agent for BRAF mutation-positive unresectable or metastatic melanoma.  
  - In combination with ipilimumab in patients for patients with unresectable or metastatic melanoma.  
- Metastatic non-small cell lung cancer with progression on or after platinum-based chemotherapy. Patients with EGFR or ALK genomic tumor aberrations should have disease progression on FDA-approved therapy for these aberrations prior to receiving nivolumab.  
- Patients with advanced or metastatic renal cell carcinoma with a clear cell component who received prior anti-angiogenic therapy.

**Dosage Form(s) Under Review**  
Dosage Form(s), Strength(s)  
- Injection 40 mg/4 mL  
- Injection 100 mg/10 mL

**REMS**  
☐ REMS  ☒ No REMS  ☐ Postmarketing Requirements  
See Other Considerations for additional REMS information

**Pregnancy**  
Based on its mechanism of action and data from animal studies, nivolumab can cause fetal harm when administered to a pregnant woman.  
See Special Populations for additional information

### Executive Summary

**Efficacy**  
- In metastatic melanoma in previously treated patients, higher objective response rates and durable response versus chemotherapy. In treatment naïve patients, single agent nivolumab superior to dacarbazine for overall survival in BRAF wild-type. In treatment naïve BRAF mutated, nivolumab and nivolumab/ipilimumab superior to ipilimumab for progression free survival. Note that in a subgroup analysis of BRAF mutated tumors, the HR for PFS crossed 1 for the analysis of nivolumab versus ipilimumab.  
- In non-small cell lung cancer in previously treated patients, nivolumab superior to docetaxel for overall survival in both non-squamous and squamous disease.  
- In renal cell cancer after 1-2 prior antiangiogenic therapies, nivolumab was
superior to everolimus for overall survival.

Safety
- Immune-related toxicities are rare but potentially serious. Early recognition and prompt treatment are key to resolution.
- Common adverse events: Melanoma (≥20%): rash (single agent); rash, pruritus, headache, vomiting, colitis (in combination with ipilimumab)
  NSCLC (≥20%): fatigue, musculoskeletal pain, decreased appetite, cough, Constipation
- While the overall percentage of patients with a grade 3 or 4 adverse event is over 20% in most clinical trials, the incidence of each grade 3 or 4 events is small.
- Discontinuation rates for adverse events was generally less than in the comparator arm.

Projected Place in Therapy
- As this is an evolving class of drugs, place in therapy should be limited to FDA indications.

Background

Purpose for review
The purposes of this monograph are to (1) evaluate evidence of safety, tolerability, efficacy, cost, and other pharmaceutical issues that would be relevant to evaluating nivolumab for possible addition to the VA National Formulary; (2) define its role in therapy; and (3) identify parameters for its rational uses in the VA.

Issues to be determined:
- Evidence of need?
- Does nivolumab offer advantages to currently available alternatives?
- Does nivolumab offer advantages over current VANF agents?
• What safety issues need to be considered?
• Does nivolumab have specific characteristics best managed by the non-formulary process, prior authorization, criteria for use?

### Efficacy (FDA Approved Indications)

#### Literature Search Summary

A literature search was performed on PubMed/Medline (1966 to October 2015) using the search term nivolumab. The search was limited to the Pub Med Clinical Queries Filter for Therapy (specific/narrow and sensitive/broad) and studies performed in humans and published in the English language. Reference lists of review articles and evidence based databases and treatment guidelines were searched for relevant clinical trials. All randomized controlled trials published in peer-reviewed journals were included.

Updated March 2016

Updated version may be found at www.pbm.va.gov or PBM INTRAnet
In patients with metastatic melanoma that was previously treated, including patients with BRAF wild type and V600 mutations, nivolumab produced higher overall response rates versus investigator’s choice of chemotherapy.

The responses in the nivolumab arm were durable as the median duration of response has not been reached versus a duration of response of 3.6 months for chemotherapy. This pattern of durable responses is similar to other immunotherapies. The results of the overall survival analysis are not yet available.

In treatment naïve patients with unresectable or metastatic melanoma without BRAF mutation, nivolumab was superior versus dacarbazine in overall survival with a median overall survival not yet reached versus 10.8 months with dacarbazine. The survival advantage was irrespective of PD-L1 expression.

In treatment naïve patients with unresectable or metastatic melanoma with a BRAF mutation, PFS was improved in patients receiving nivolumab or nivolumab plus ipilimumab versus ipilimumab itself. The PFS in the combination arm was also improved compared to nivolumab. PFS in patients whose tumors express PD-L1 was the same in the combination or nivolumab arm and was better than the ipilimumab arm. PFS was better in the combination arm versus nivolumab or ipilimumab in patients whose tumors did not express PD-L1. The results of the co-primary outcome of overall survival are not yet available.

Note that in a subgroup analysis of BRAF mutated tumors, the HR for PFS crossed 1 for the analysis of nivolumab versus ipilimumab.

Updated March 2016

Updated version may be found at [www.pbm.va.gov](http://www.pbm.va.gov) or [PBM INTRAnet](http://www.pbm.va.gov)
Nivolumab Monograph

In patients with previously treated non-squamous non-small cell lung cancer, nivolumab increased overall survival compared to standard docetaxel therapy.

The overall survival advantage was seen at 12 months and 18 months.

Objective response, improved PFS and improved overall survival were not associated with PD-L1 expression.

In patients with previously treated squamous non-small cell lung cancer, nivolumab increased overall survival compared to standard docetaxel therapy.

The overall survival advantage was also seen at the 12 month mark.

The median duration of response has not yet been reached.

Objective response, improved PFS and improved overall survival were not associated with PD-L1 expression.

Subjects who received adjuvant or neoadjuvant platinum-doublet chemotherapy (after surgery and/or radiation therapy) and developed recurrent or metastatic disease within 6 months of completing therapy were eligible. However, patients with recurrent disease > 6 months after adjuvant or neoadjuvant platinum based chemotherapy also needed to subsequently progress during or after a platinum doublet regimen given to treat the recurrence to be eligible for nivolumab.

In patients with advanced or metastatic renal cell carcinoma with a clear cell component who progressed on 1-2 prior antiangiogenic therapies, nivolumab increased overall survival versus the mTOR inhibitor everolimus. The point
estimate for overall survival favored nivolumab in multiple subgroups, but the confidence intervals crossed 1 for the following groups: favorable MSKCC score, 2 previous antiangiogenic regimens, patients in western Europe and rest of the world, Age <65 years old, and female sex.

- Quality of life scores, Functional Assessment of Cancer Therapy Kidney Symptom Index-Disease-Related Symptoms (FKSI-DRS), in the nivolumab group increased (improved) over time (weeks 32-104) and differed significantly from the scores in the everolimus treated patients which decreased (worsened) over time.
- There was a numerical overall survival advantage for nivolumab irrespective of PD-L1 expression, however for those with PD-L1 1% or greater the 95% confidence interval crossed 1 which did not occur in those with PD-L1 <1%.

### Potential Off-Label Use
- Ovarian carcinoma
- Relapsed/refractory Hodgkin’s Lymphoma (CheckMate 039)
- Glioblastoma Multiforme
- Hepatocellular Carcinoma
- Bladder/urothelial ancer
- Head and Neck Cancer
- Colorectal carcinoma
- Gastric cancer
- Triple negative breast cancer
- Non-Hodgkin’s lymphoma
- Esophageal cancer
- Adjuvant melanoma
- Nivolumab + chemo in NSCLC
- Nivolumab + ipilimumab in Renal Cell Cancer
- Nivolumab + ipilimumab in NSCLC

### Safety

### Safety Considerations
- Immune-mediated reactions are the most significant safety concerns for this drug. Like with other immune-
modulators, early recognition and initiation of treatment are key.

**Adverse Reactions**

**Common adverse reactions**
- Melanoma (≥20%): rash (single agent); rash, pruritus, headache, vomiting, colitis (in combination with ipilimumab)
- NSCLC (≥20%): fatigue, musculoskeletal pain, decrease appetite, cough, constipation
- Renal cell (≥20%): asthenic conditions, cough, nausea, rash, dyspnea, diarrhea, constipation, decreased appetite, back pain, arthralgia

**Death/Serious adverse reactions**
- Melanoma (2% - <5%): abdominal pain, hyponatremia, increased aspartate aminotransferase, increased lipase. (≥10%): rash
- Melanoma in combination with ipilimumab: colitis, diarrhea not treated with steroids, increased ALT, pneumonitis, AST increase, pyrexia; in at least 20%: rash, pruritus, headache, vomiting, colitis.
- NSCLC (at least 2%): pneumonia, pulmonary embolism, death due to limbic encephalitis
- Renal cell (at least 2%): acute kidney injury, pleural effusion, pneumonia, diarrhea, hypercalcemia

**Discontinuations due to adverse reactions**
- Melanoma (single): 6.8 vs 11.7%
- Melanoma (combination): 52.1% vs 24.3% (ipi); 36.4% vs 14.8% (ipi) vs 7.7% (nivolumab)
- NSCLC: 3-5% vs 10-15% (docetaxel)
- Renal cell: 16% vs 19% (everolimus)

**Drug Interactions**

**Drug-Drug Interactions**
- No pharmacokinetic drug-drug interaction studies

**Risk Evaluation**
As of October 1, 2015

**Comments**

**Sentinel event advisories**
- None
- Sources: ISMP, FDA, TJC

**Look-alike/sound-alike error potentials**

**Other Considerations**

**Outcome in clinically significant area**
- Melanoma Previously Treated (vs chemo): ORR 31.7%; PFS 4.7 mos; OS not available
- Melanoma Treatment naïve (vs dacarbazine): OS NR vs 10.8 mos; PFS 5.1 vs 2.2 mos

Updated March 2016
Updated version may be found at www.pbm.va.gov or PBM INTRAnet
Melanoma Treatment naïve + ipilimumab: PFS 11.5 vs 6.9 mos (NI vs N); OS not available
NSCLC (nonsquamous) vs docetaxel: OS 12.2 vs 9.4 mos
NSCLC (squamous) vs docetaxel: OS 9.2 vs 6.0
Renal Cell (vs everolimus): OS 25 vs 19.6 mos

Effect Size
Melanoma Previously Treated: PFS HR 0.82 (99%CI 0.32-2.05)
Melanoma Treatment naïve: OS HR 0.42 (99%CI 0.25-0.73); PFS HR 0.43
Melanoma Treatment naïve + ipilimumab: PFS (NI vs I) HR 0.42; (N vs I) HR 0.57
(NI vs N) HR 0.74 (99.5%CI 0.60-0.92)
NSCLC (nonsquamous): OS HR 0.73 (95%CI 0.59-0.89)
NSCLC (squamous): OS HR 0.59 (95%CI 0.44-0.79)
Renal Cell: OS HR 0.73 (98.5%CI 0.57-0.93)

Potential Harms
Single agent melanoma: Grade 3 or 4 in 42%
Combination with ipilimumab in melanoma: Grade 3 or 4 in 69%
NSCLC nonsquamous: Grade 3 or 4 in 47%
NSCLC squamous: Grade 3 or 4 in 7%
Renal Cell: Grade 3 or 4 in 19%

Net Clinical Benefit
Melanoma Previously Treated: Negative
Melanoma Treatment Naïve: Moderate
Melanoma Treatment naïve + ipilimumab: Moderate
NSCLC (nonsquamous): Moderate
NSCLC (squamous): Substantial
Renal Cell: Substantial

Definitions
Outcome in clinically significant area: morbidity, mortality, symptom relief, emotional/physical functioning, or health-related quality of life
Effect Size: odds ratio, relative risk, NNT, absolute risk reduction, relative risk reduction, difference in size of outcomes between groups, hazard ratio
Net Clinical Benefit: Substantial (high benefit with low risk of harm), moderate (high benefit with high risk of harm), minimal (low benefit with low risk of harm), negative (low benefit with high risk of harm)

Dosing and Administration
- Refer to the package insert for full dosing information and recommended dose modifications
- Melanoma (single agent): Nivolumab 3mg/kg as an intravenous infusion over 60 minutes every 2 weeks until disease progression or unacceptable toxicity.
- Melanoma in combination with ipilimumab: Nivolumab 1mg/kg as an intravenous infusion over 60 minutes, followed by ipilimumab on the same day, every 3 weeks for 4 doses. Subsequent doses of nivolumab is 3 mg/kg as an intravenous infusion over 60 minutes every 2 weeks until disease progression or unacceptable toxicity.
- NSCLC: Nivolumab 3mg/kg as an intravenous infusion over 60 minutes every 2 weeks.
- Renal cell carcinoma (clear cell): Nivolumab 3 mg/kg as an intravenous infusion over 60 minutes every 2 weeks.

Special Populations (Adults)

Elderly
- No differences in safety or efficacy in 2nd line single-agent trial in melanoma (35% >65 yrs old and 15% ≥75 yrs old) or 2nd line single agent trial in non-squamous NSCLC (37% >65 yrs old and 7% ≥75 yrs old). In combination with ipilimumab, too few patients >65 yrs old to evaluate for efficacy and safety.

Pregnancy
- Risk summary: Based on mechanism of action and animal data, nivolumab can cause fetal harm when given to a pregnant female. In animals given nivolumab from onset of organogenesis through delivery there was an increased incidence of abortion and premature infant death. Nivolumab is an immunoglobulin G4 and human IgG4 is known to cross placenta and can be transmitted from mother to fetus. There is no available human data.

Lactation
- Risk Summary: It is not known if nivolumab is present in breast milk. Because drugs, including antibodies are excreted in breast milk and due to the potential serious adverse reactions in nursing infants from nivolumab, women should be advised to stop breastfeeding during therapy with nivolumab.

Females and Males of Reproductive
- Advise females of reproductive potential to use effective
Potential contraception during nivolumab therapy and for at least 5 months following the last dose of nivolumab.

Renal Impairment
- Based on population pharmacokinetics, no dose adjustment is recommended in patients with renal impairment.

Hepatic Impairment
- Based on population pharmacokinetics, no dose adjustment is recommended for mild hepatic impairment. Nivolumab has not been studied in patients with moderate or severe hepatic impairment.

Pharmacogenetics/genomics
- No data identified

Projected Place in Therapy
- Metastatic melanoma: Current FDA approved choices for therapy for metastatic melanoma that is refractory to ipilimumab and/or BRAF inhibition if BRAF V600 mutation positive, include dacarbazine and intereleukin-2, both providing limited benefit and considerable toxicity. For front-line therapy, FDA approved drugs include dacarbazine, interleukin-2, interferon, ipilimumab, pembrolizumab and TKIs for tumors with actionable mutations: vemurafenib, dabrafenib, trametinib, and cobimetinib.
- Lung cancer is one of the top 2 cancers in the VA.
- In non-squamous non-small cell lung cancer that has progressed on a platinum based chemotherapy regimen, there are a number of drugs available for use in this setting. Subsequent therapy in the context of platinum failure does not depend on the tumor molecular profile.
- In squamous non-small cell lung cancer that has progressed on 1 prior platinum based chemotherapy, choices for subsequent therapy are more limited.
- In patients with renal cell carcinoma with a clear cell component, therapy following antiangiogenic therapy is everolimus, an mTOR inhibitor.
- The overall quality of the evidence for nivolumab is high. Some caveats including the lack of availability of overall survival data for previously treated patients with melanoma and in treatment naïve patients with melanoma and a BRAF mutation until sometime in 2016. The quality of data in non-small cell lung cancer is also high, but there is some question about choosing the right patients especially in the non-squamous setting. In renal cell with clear cell component, there are more limited choices with good data for 2nd or 3rd line therapy after antiangiogenic therapy. The quality of data with nivolumab is high and an FDA indication in this setting is expected shortly.
- On ongoing question in this class is choosing the best patients for therapy. Although PD-L1 expression has been tested in clinical trials there is no validation of the staining method and therefore no standardized method for measurement. There is also no standard interpretation of the correct cut-point for declaring PD-L1 expression positivity: in clinical trials in this class of drugs 1%, 5%, 10% and 50% have all been utilized. There are other biomarkers that may become important in the future with predicting which patients are more likely to respond (e.g. tumor-infiltrating lymphocytes and DNA mismatch-repair deficiency).
- Place in therapy should generally follow the current FDA indications until we have more detailed information on using biomarkers to delineate subpopulations to treat or not treat.

### Appendix A: GRADEing the Evidence

<table>
<thead>
<tr>
<th>Designations of Quality</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>High</strong></td>
<td>Evidence includes consistent results from well-designed, well-conducted studies in representative populations that directly assess effects on health outcomes (2 consistent, higher-quality randomized controlled trials or multiple, consistent observational studies with no significant methodological flaws showing large effects).</td>
</tr>
<tr>
<td><strong>Moderate</strong></td>
<td>Evidence is sufficient to determine effects on health outcomes, but the number, quality, size, or consistency of included studies; generalizability to routine practice; or indirect nature of the evidence on health outcomes (1 higher-quality trial with &gt; 100 participants; 2 higher-quality trials with some inconsistency; 2 consistent, lower-quality trials; or multiple, consistent observational studies with no significant methodological flaws showing at least moderate effects) limits the strength of the evidence.</td>
</tr>
<tr>
<td><strong>Low</strong></td>
<td>Evidence is insufficient to assess effects on health outcomes because of limited number or power of studies, large and unexplained inconsistency between higher-quality studies, important flaws in study design or conduct, gaps in the chain of evidence, or lack of information on important health outcomes.</td>
</tr>
</tbody>
</table>

Appendix B: Approval Endpoints (use for oncology NMEs)

Table 1. A Comparison of Important Cancer Approval Endpoints

<table>

</tr>
</tbody>
</table>

*Adequacy as a surrogate endpoint for accelerated approval or regular approval is highly dependent upon other factors such as effect size, effect duration, and benefits of other available therapy. See text for details.
